CE95400 - Watchdog Timer Reset and Interrupt for PSoC® 41xx/42xx Devices

Objective

This example demonstrates how to use the watchdog in PSoC 41xx/42xx devices to both reset the system and wake up from the Deep Sleep low power mode.

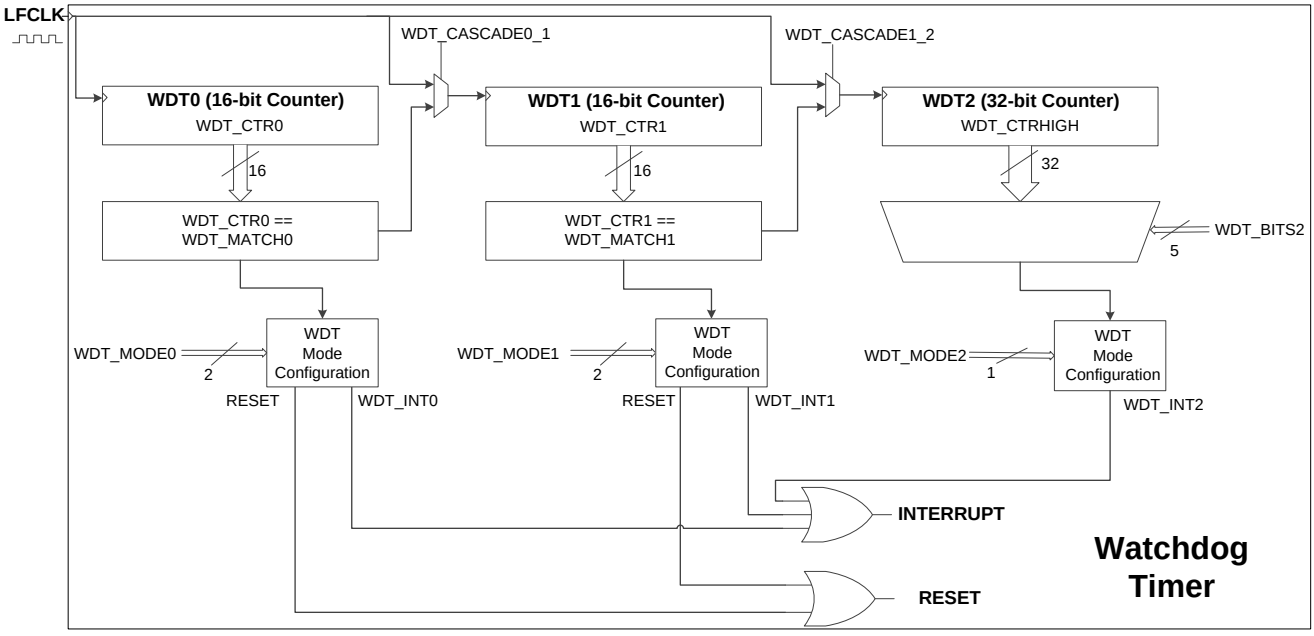
Overview

There are three examples that can run on the CY8CKIT-042 Pioneer kit; however, these can be ported to other boards that contain LEDs and buttons.

- Project #1 shows how to reset the system when the program is out-of-control due to unexpected inputs or conditions. It also shows how to store log data into flash before reset, which can be read with PSoC Programmer™ for fault analysis.
- Project #2 shows how to wake the system from deep sleep, which is a critical function for low-power application design.
- Project #3 combines functions of above two projects to demonstrate the cascade feature of the watchdog timer.

Figure 1 illustrates the block diagram of the watchdog timer in PSoC 4100/4200 devices.

Figure 1. Watchdog Block Diagram for PSoC 4100/4200 Devices



Note The watchdog block in the PSoC 4000 family is simpler than in the PSoC 4100/4200 family. It has only one 16-bit counter. See KBA91373 - Watchdog Timer in the PSoC® 4000 Family for a code example for the PSoC 4000 family. See the Watchdog Timer section in the System Reference Guide to know more about the PSoC 4 watchdog block function and API.

Requirements

Tool: PSoC Creator 3.0 SP2 or later version.

Programming Language: C (GCC 4.7.3), ARM® Cortex®-M0 Assembler

Associated Parts: PSoC 4100/4200 family

Related Hardware: CY8CKIT-042

Design

For PSoC 41xx/42xx devices, once the watchdog timer is enabled, it counts the 32-kHz internal clock “LFCLK” with the internal counter. If a match value is set by writing to the MATCH register, the watchdog timer generates an interrupt when the counter value is equal to the match value. If the counter value is cleared before reaching the match value, the interrupt is never generated and the counter value is cleared. This operation is called “clear the watchdog counter”.

There are some rules for clearing the watchdog counter:

- It must be done before counter value reaches the match value. For functions that have long execution times, you may have to insert multiple clearing operations during function execution.
- It should NOT be done in the interrupt service routine (ISR). Otherwise, the main loop may be out-of-control, but the interrupt is still generated periodically. The watchdog interrupt is cleared in the ISR, which prevents the watchdog from generating a system reset when this fault condition occurs.
- Clearing the watchdog counter may require a little time to settle, which can be found in the device datasheet or technical reference menu.

If the desired clearing operation is halt due to a fault condition such as the main loop entering an infinite loop execution and never exiting, the watchdog generates the interrupt. For PSoC 41xx/42xx devices, a system reset happens for the third continuous unhandled interrupt (interrupt flag bit is not cleared).

Moreover, you can disable generating the system reset and use the watchdog timer to generate periodic interrupts that can wake system from the deep sleep mode. This feature is extremely useful for low-power designs.

Project #1 – Using Watchdog Timer to Reset the System

The watchdog timer is configured to generate an interrupt every second. The watchdog counter is cleared periodically in the main loop. If the switch button ‘SW2’ is pressed (simulating a fault condition), the clearing operation is stopped. After three seconds (the third continuous unhandled interrupt), the system is reset.

For the first watchdog interrupt (the counter value equal to the match value), some log data (integers from 0 to 127) is stored in the last row of the internal flash. This log data can be read with PSoC Programmer for fault analysis.

Three LEDs indicate the system status:

- Green LED: Turns ON when the system is working normally (the switch SW2 is not pressed)
- Blue LED: Turns ON while the switch SW2 is pressed
- Red LED: Turns ON for one second to indicate that the system was just reset by the watchdog timer

Figure 2 shows the PSoC Creator schematic and Figure 3 illustrates the firmware flow for this project.

Figure 2. Creator Schematic for Project #1

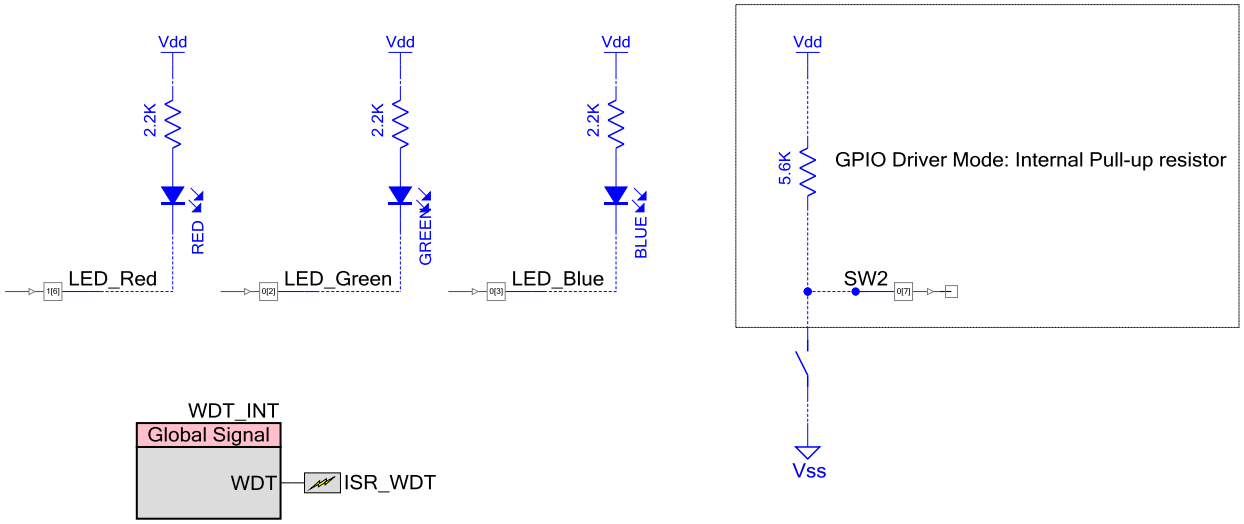


Figure 3. Firmware Flow for Project #1

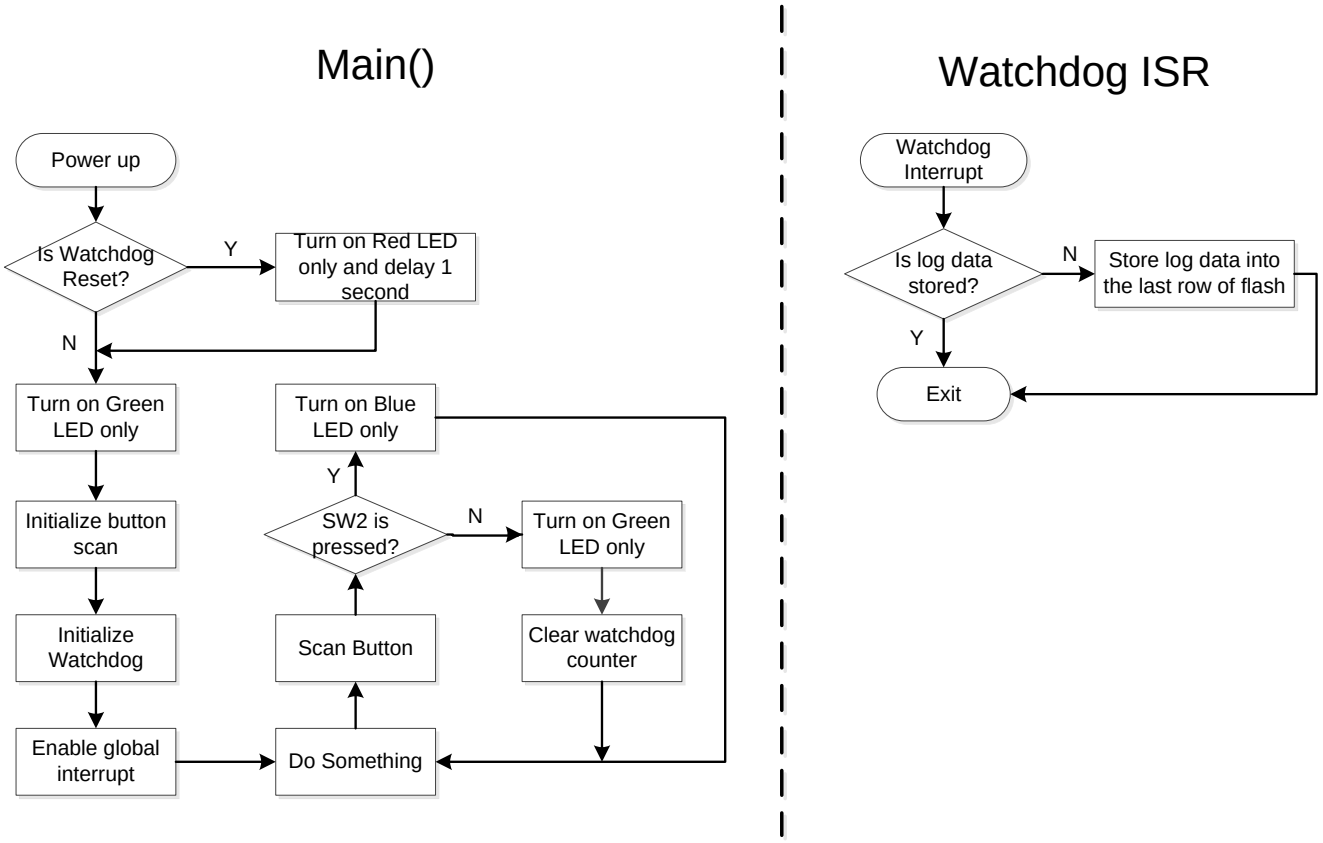

Project #2 – Wakeup from Deep Sleep

The watchdog timer is configured to generate an interrupt every 250 milliseconds. This interrupt wakes the system from deep sleep mode. THe system delays 500 milliseconds by calling CyDelay functions and then goes into deep sleep again.

Two LEDs are used to indicate the system status. Before the system enters deep sleep mode, only the green LED is turned ON and is kept ON during the deep-sleep time. After the system is woken by a watchdog timer interrupt, only the red LED is turned ON. It is kept ON during the firmware delay. Then, only the green LED is turned ON and system goes into deep sleep again.

Figure 4 shows the PSoC Creator schematic and Figure 5 illustrates the firmware flow for this project.

Figure 4 Creator Schematic for Project #2

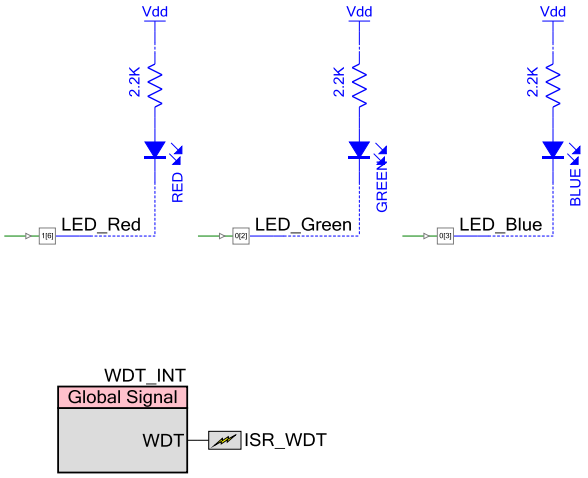

Figure 5 Firmware Flow for Project #2

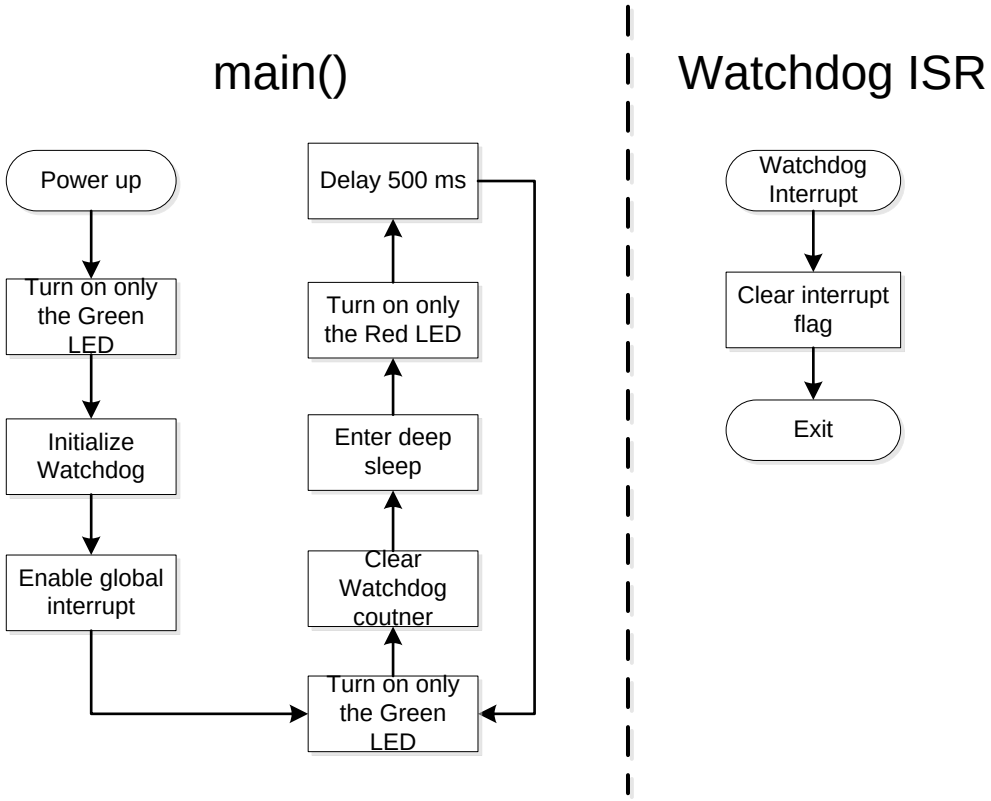

Project #3 – Wakeup from Sleep with System Reset Enabled

The watchdog timer in PSoC 41xx/42xx devices has three 16-bit counters. Counter 0 and counter 1 can be configured as cascaded. Counter 0 is configured to generate an interrupt only (no system reset) when the counter value is equal to the match value (match event). Counter 1 counts the match event from Counter 0 and compares its value with the match value in Counter 1 register. When they are equal, it generates an interrupt. If three continuous interrupts are not handled, a system reset happens. Refer to PSoC 41xx/42xx PSoC 4 Technical Reference Manuals (TRM) for more details.

This code example shows how to use this feature to combine the system reset and sleep wakeup together. These two functions have been shown separately in the earlier two projects.

Counter 0 is configured to generate an interrupt every 250 ms, which wakes the system from deep sleep. Counter 1 is configured to generate an interrupt every 1 second. If the interrupt is not handled for three continuous times, the system is reset and log data is stored into the last row of internal flash as Project #1 shows.

Three LEDs indicate the system status:

- Green LED: Turns ON when the system is working normally (the switch SW2 is not pressed)
- Blue LED: Turns ON when the switch SW2 is pressed
- Red LED: Turns ON to indicate that the system was just reset by the watchdog timer or system has woken up from deep sleep

Figure 6 shows the PSoC Creator schematic and Figure 7 illustrates the firmware flow for this project.

Figure 6 Creator Schematic for Project #3

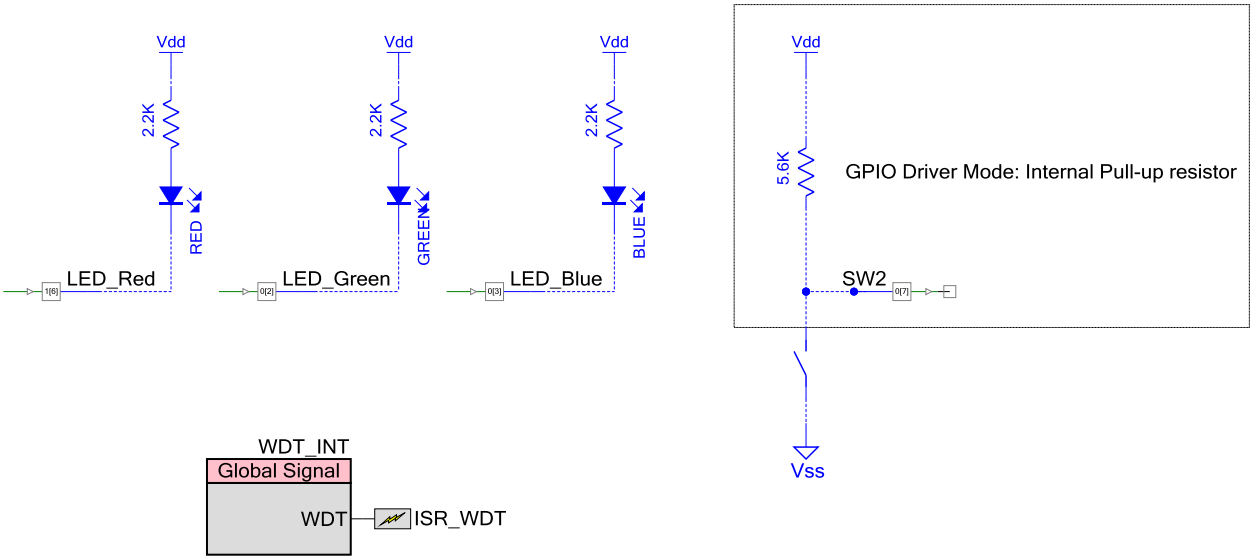

Figure 7 Firmware Flow for Project #3

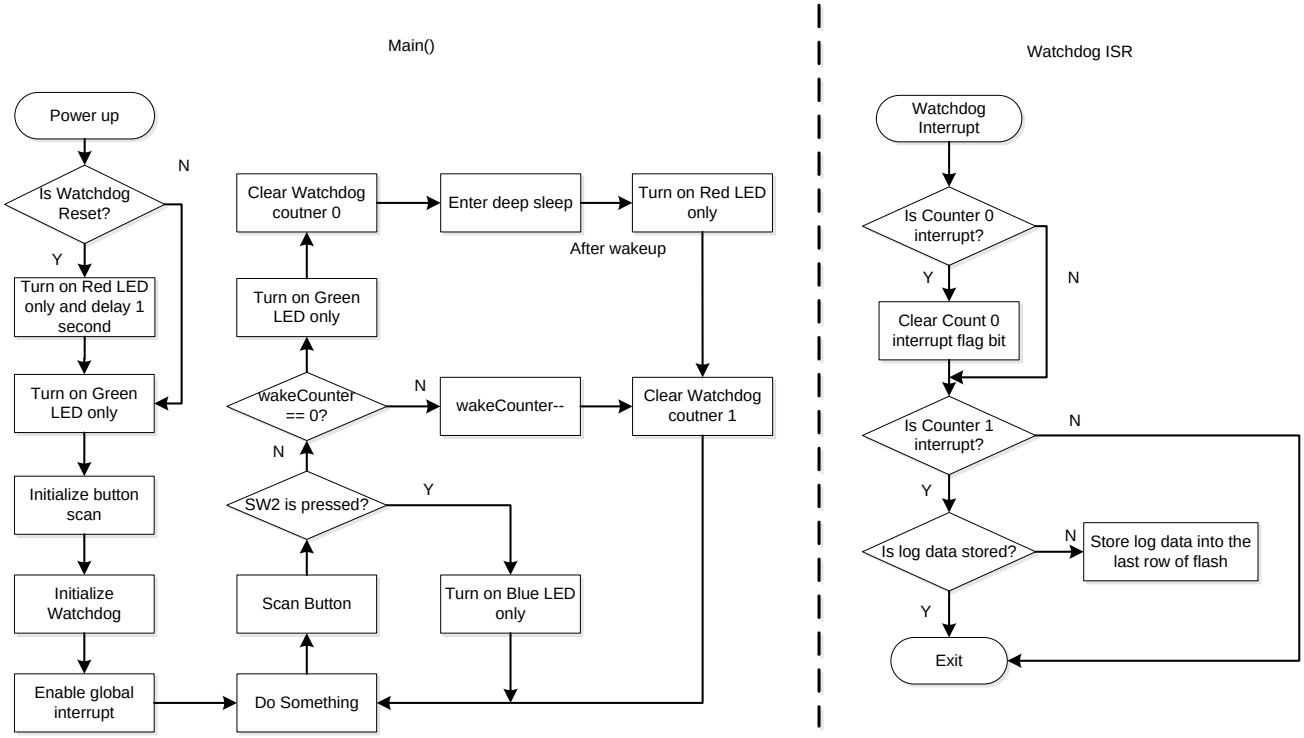


Design Considerations

The pull-up resistor for SW2 button is inside the chip GPIO block. No external resistor is used.

CY8CKIT-042 uses a three-in-one LED package that contains red, green, and blue LEDs. These may be separated in other kits, or even replaced by other kinds of display method, such as a segment LCD.

This design can be extended to run on other kits, such as the CY8CKIT-001 with CY8CKIT-038

Hardware Setup

For basic kit board setup, see the corresponding Kit Guide. For setup with a specific kit, do the following:

1. CY8CKIT-042: No special settings are required for this kit.
2. CY8CKIT-038: This kit works with CY8CKIT-001 to evaluate PSoC 4 functions. You can choose three of the four LEDs (LED1 through 4) on CY8CKIT-001 to replace the RGB LED on CY8CKIT-042. Use three wires to connect LEDs to pin sockets near the breadboard on CY8CKIT-001. You can also choose SW1 or SW2 on CY8CKIT-001 to replace the SW2 button on CY8CKIT-042. In addition, use one wire to connect SW1 or SW2 to the pin socket near the breadboard on CY8CKIT-001. See CY8CKIT-001 user guide for more details.

Software Setup

No special software setup is required. All supported compilers can be used with any optimization.

Components

Table 1 lists the PSoC Creator Components used in this example as well as the hardware resources used by each.

Table 1. List of PSoC Creator Components

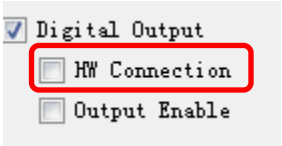
Component	Hardware Resources
Digital Output Pin	Three PSoC 4 GPIO configured as digital output without pull-up or pull-down resistors
Digital Input Pin	One PSoC 4 GPIO configured as digital input with a pull-up resistor
Interrupt	One interrupt service routine with the highest priority
Global Signal	Connect the WDT interrupt to the Interrupt Component
Pin	Three pins for LED indicators; one pin for switch button detection

Parameter Settings

Digital Output Pins:

Clear the “HW Connection” option to prevent build errors.

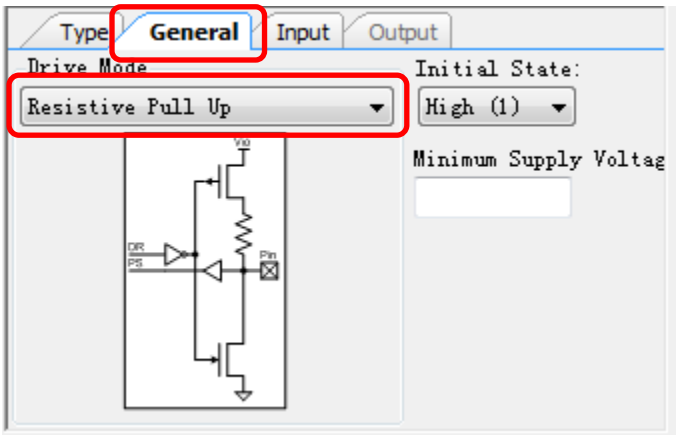
Figure 8. Uncheck HW Connection



Digital Input Pins:

1. Clear the “HW Connection” option to prevent build errors.
2. Set the drive mode as “Resistive Pull Up” in the General Tab:

Figure 9. Set Pull-up Resistor Drive Mode



Design-Wide Resources

Figure 10 and Figure 11 show the pin assignments for each example. No other design-wide resource needs to be changed from its default setting.

Figure 10. Pin Assignment for Project #1 and Project #3

Name	Port	Pin
LED_Blue	P0[3]	27
LED_Green	P0[2] SCB0:SPI:SS3	26
LED_Red	P1[6]	43
SW2	P0[7] SCB1:SPI:SS0, WAKEUP	31

Figure 11 Pin Assignment for Project #2

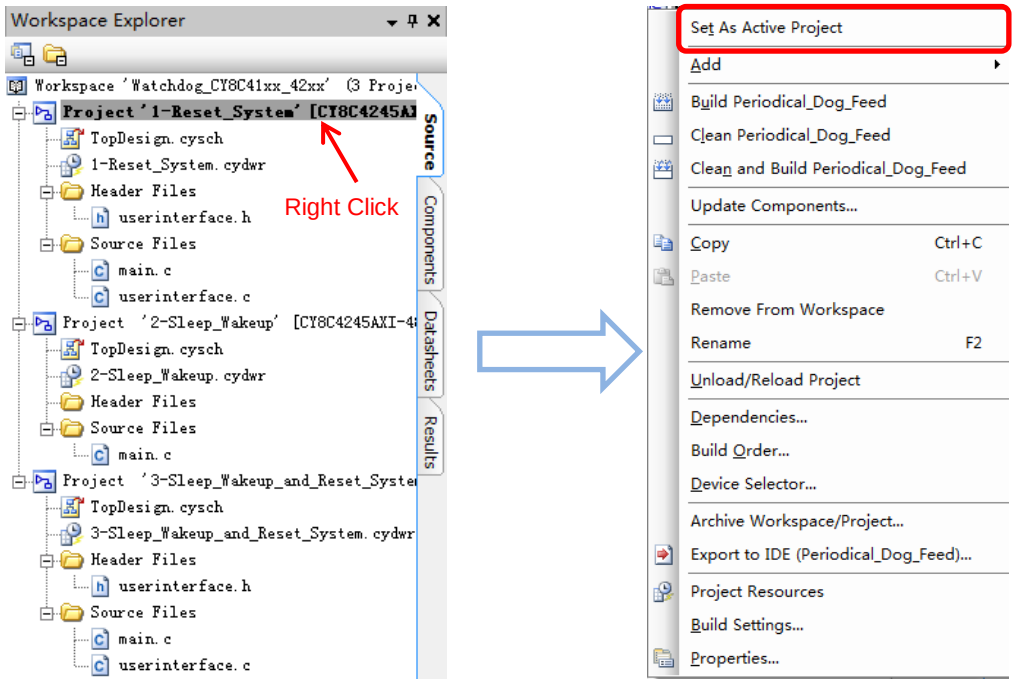
Name	Port	Pin
LED_Blue	P0[3]	27
LED_Green	P0[2] SCB0:SPI:SS3	26
LED_Red	P1[6]	43

Operation

Project #1 – Using the Watchdog Timer to Reset the System

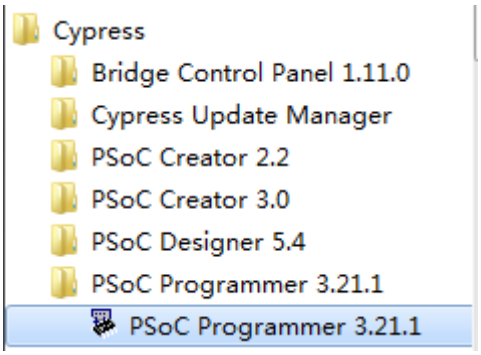
1. In the Workspace Explorer, right-click the “Project ‘1-Reset_System’” and select “Set As Active Project”. See Figure 12.

Figure 12. Choose Project #1 as Active Project



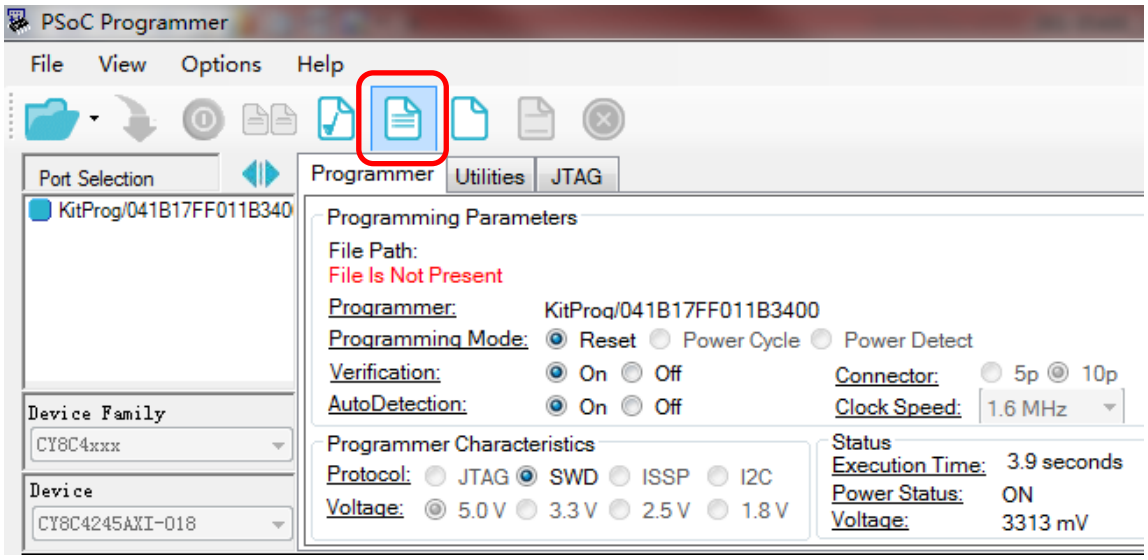
2. Build the project to generate hex file.
3. Connect the PC to CY8CKIT-042 J10 with the USB cable.
4. Download the hex file to the PSoC 4 chip.
5. Keep the USB cable connection for power supply.
   a) Press the Reset button on the kit and observe the LED status on the top right corner of CY8CKIT-042. The green LED first blinks and then turns ON, which means that the system has reset and entered the normal working stage. Until a further input, the green LED keeps in the ON state.
   b) Press the SW2 button and observe the status LED. The green LED is turned OFF and the blue LED is turned ON. After the blue LED is turned ON, release the SW2 button. The green LED is turned ON again and blue LED is turned OFF. The blue LED indicates that the button SW2 is pressed.
   c) Press and hold SW2 again for more than three seconds. Observe the status LED during the operation. The blue LED is turned on at first; after approximately three seconds, the red LED is turned ON for approximately 1 second, and then the blue LED is turned ON again. The red LED indicates that system was just reset by the watchdog because the watchdog counter was not cleared.
   d) Whenever the SW2 button is released, the green LED is turned ON.
   e) Press and hold SW2 again. Observe the status LED during the operation. The red LED is turned ON periodically, which means that the system continues to reset.
6. Launch PSoC Programmer from the Start menu as shown in Figure 13. The operation of PSoC Programmer can be found in User Guide.

Figure 13. Launch PSoC Programmer



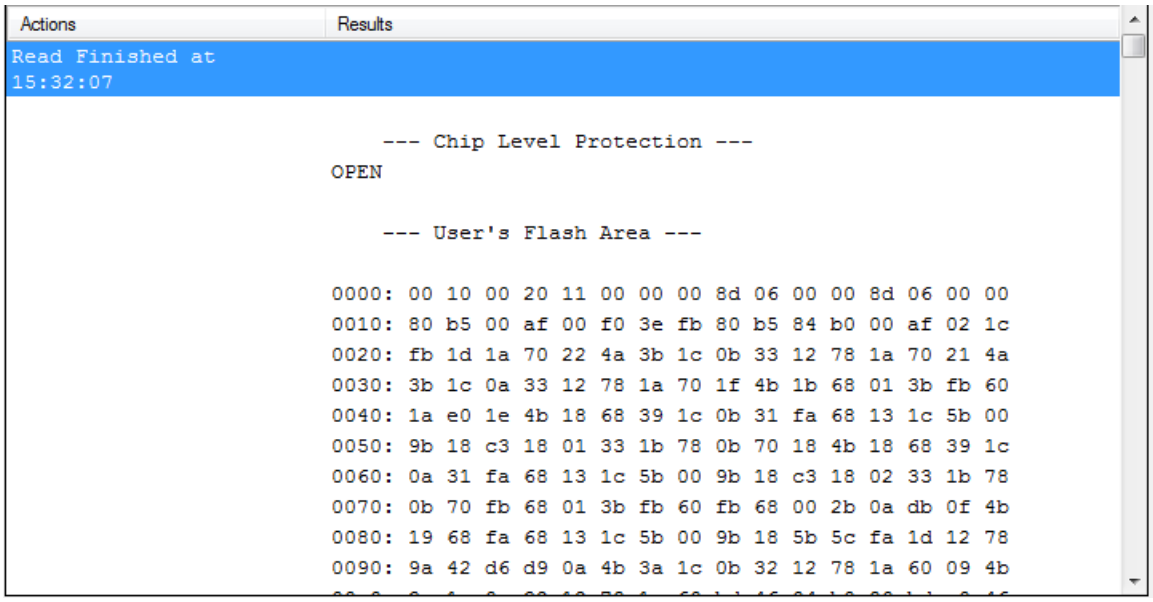
7. In PSoC Programmer, click the “Read” button to read the flash data (red box in Figure 14). Pay attention to the PSoC Programmer setting shown in Figure 14.

Figure 14. Read Operation in PSoC Programmer



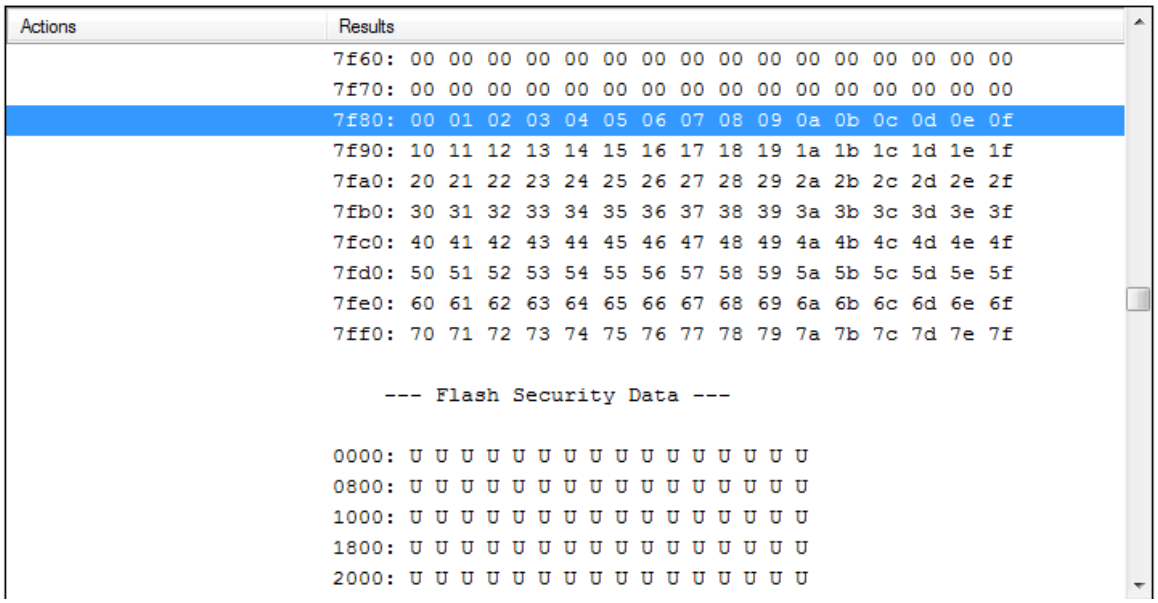
The flash data is read and display in the result window of PSoC Programmer. Figure 15 shows the data at beginning rows of flash.

Figure 15. Data in Beginning Rows of Flash



8. Scroll down the flash data to the rows at the end of flash. You can see the log data that was stored in flash when the watchdog reset happened. In this code example, they are the incremental integer from 0 to 128 (Figure 16).

Figure 16. Log Data after Watchdog Reset Happens

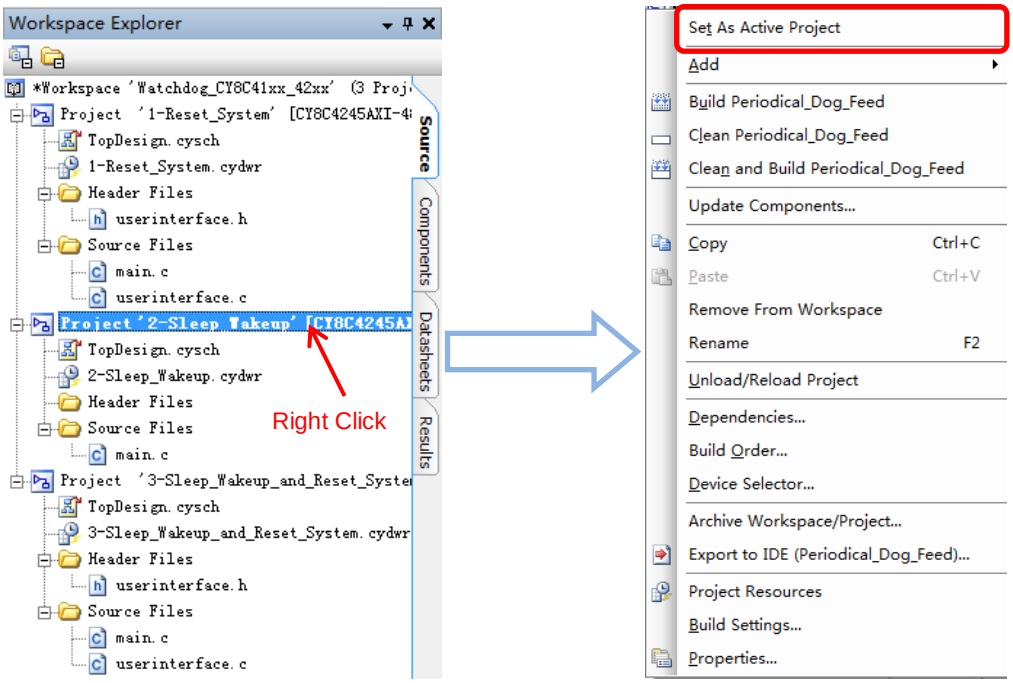


Note: This log can be only seen after a watchdog reset has happened (after the red LED is turned ON and no new hex file is programmed in to flash). Pressing the reset button has no effect on this log data.

Project #2 – Wakeup from Deep Sleep

1. In the Workspace Explorer, right-click the “Project ‘2-Sleep_Wakeup’” and select “Set As Active Project” (see Figure 17).

Figure 17. Choose Project #2 as Active Project



2. Build the project to generate the hex file.
3. Connect the PC to CY8CKIT-042 J10 with the USB cable.
4. Download the hex file to PSoC 4 chip.
5. Keep the USB cable connection for power supply.
   a) Press the Reset button on the kit and observe the LED status on the top right of CY8CKIT-042. The green LED first blinks and then turns ON, which means that the system has reset and entered the normal working stage.
   b) Later, the green LED is turned OFF and the red LED is turned ON. This sequence is repeated indefinitely. The red LED indicates that system has just woken up from deep sleep by a watchdog interrupt.

Project #3 – Wakeup from Sleep with System Reset Enabled

1. In Workspace Explorer, right-click the “Project ‘3-Sleep_Wakeup_and_Reset_System’” and select “Set As Active Project” (see Figure 18).
2. Build the project to generate the hex file.
3. Connect the PC to CY8CKIT-042 J10 with the USB cable.
4. Download the hex file to PSoC 4 chip.
5. Keep the USB cable connection for power supply.
   a) Press the Reset button on the kit and observe the LED status on the top right corner of CY8CKIT-042. The green LED first blinks and then turns ON, which means that the system has reset and entered the normal working stage.
   b) If SW2 is not pressed, the system behaves as described in Project #2 – Wakeup from Deep Sleep.
   c) If SW2 is pressed, the system behaves as described in Project #1 – Using the Watchdog Timer to Reset the System.

Figure 18. Choose Project #3 as Active Project
